AMENDMENTS TO THE CLAIMS

1. (Currently Amended) A public key generation apparatus including:

a random number generator for generating a random number ka that holds a relationship $0 < ka < q$, where an element in a finite group F for which multiplication is defined is g, and an order that is a prime number of the element g is q; and

a public key generator for calculating a public key ya in the finite group F from the random number ka, the element g, and the prime number q,

wherein at least said random number generator and said public key generator are formed on one semiconductor integrated circuit ~~and~~ so as to prevent diversion or alteration of an arithmetic algorithm of the public key generator,

wherein the random number generator generates a new random number after the calculation of the public key ya is completed so that the public key ya becomes a function of the random number,

wherein a controller of a first user as a distribution source of the public key controls the random number generator and the public key generator to obtain the public key ya, and transmits the obtained public key ya to a second user as a distribution destination of the public key, and

wherein the arithmetic algorithm of the public key generator is not revealed outside of the one semiconductor integrated circuit.

2. (Previously Presented) The public key generation apparatus of Claim 1, wherein said public key generator calculates the public key ya in the finite group F by a formula:

ya = g^ka mod q, using the random number ka, the element g, and the prime number q.

3. (Previously Presented) The public key generation apparatus of Claim 1, wherein

when the finite group F is an elliptic curve E(F) in a finite field, and an element of the elliptic curve E(F) is G,

said public key generator calculates the public key ya on the elliptic curve E(F) by a formula: ya = kaG mod q, using the random number ka, the element G, and the prime number q.

4. (Canceled)

5. (Currently Amended) A shared key generation apparatus including:

a random number generator for generating a random number ka that holds a relationship $0 < ka < q$, where an element in a finite group F for which multiplication is defined is g, and an order that is a prime number of the element g is q; and

a shared key generator for calculating a shared key Ka in the finite group F from a public key yb that is generated from a random number kb which holds a relationship $0 < kb < q$ and is generated by a second user as a distribution destination of the shared key, and the random number ka,

wherein at least said random number generator and said shared key generator are formed on one semiconductor integrated circuit ~~and~~ so as to prevent diversion or alteration of an arithmetic algorithm of the shared key generator,

wherein the random number generator generates a new random number after the calculation of the public key ya is completed so that the shared key Ka becomes a function of the random number,

wherein a controller of a first user as a distribution source of the shared key obtains the public key yb from the second user as the shared key distribution destination, and controls the random number generator and the shared key generator to derive the shared key Ka, and

wherein the arithmetic algorithm of the shared key generator is not revealed outside of the one semiconductor integrated circuit.

6. (Previously Presented) The shared key generation apparatus of Claim 5, wherein

said shared key generator calculates the shared key Ka in the finite group F by a formula: Ka = yb^ka mod q, using the public key yb = g^kb mod q which is generated by the second user as the shared key distribution destination and the random number ka.

7. (Previously Presented) The shared key generation apparatus of Claim 5, wherein

when the finite group F is an elliptic curve E(F) in a finite field and an element of the elliptic curve E(F) is G,

said shared key generator calculates the shared key Ka on the elliptic curve E(F) by a formula: Ka = kayb mod q, using the public key yb = kbG mod q which is generated on the elliptic curve E(F) from the random number kb by the second user as the shared key distribution destination, and the random number ka.

8. (Canceled)

9. (Currently Amended) A key exchange apparatus including:

a random number generator for generating a random number ka that holds a relationship $0 < ka < q$, where an element in a finite group F for which multiplication is defined is g, and an order that is a prime number of the element g is q;

a public key generator for calculating a public key ya in the finite group F from the random number ka, the element g, and the prime number q; and

a shared key generator for calculating a shared key Ka in the finite group F on the basis of the public key yb generated from a random number kb which holds a relationship $0 < kb < q$ and is generated by a second user as a distribution destination of the shared key, and the random number ka,

wherein at least said random number generator, said public key generator, and said shared key generator are formed on one semiconductor integrated circuit ~~and~~ so as to prevent diversion or alteration of arithmetic algorithms of the public key generator and the shared key generator,

wherein the random number generator generates a new random number after the calculation of the public key ya and the calculation of the shared key Ka are both completed so that the public key ya and the shared key Ka become functions of the random number,

wherein a controller of a first user as a distribution source of the shared key controls the random number generator and the public key generator to obtain the public key yb, and controls the shared key generation unit to derive the shared key Ka, and

wherein the arithmetic algorithms of the public key generator and the shared key generator are not revealed outside of the one semiconductor integrated circuit.

10. (Previously Presented) The key exchange apparatus of Claim 9, wherein

said public key generator calculates the public key ya in the finite group F by a formula: ya = g^ka mod q, using the random number ka, the element g, and the prime number q, and

said shared key generator calculates the shared key Ka in the finite group F by a formula: Ka = yb^ka mod q, using the public key yb = g^kb mod q which is generated in the finite group F by the second user as the shared key distribution destination using the random number kb, and the random number ka.

11. (Previously Presented) The key exchange apparatus of Claim 9, wherein

when the finite group F is an elliptic curve E(F) in a finite field, and an element of the elliptic curve E(F) is G,

said public key generator calculates the public key ya on the elliptic curve E(F) by a formula: ya = kaG mod q, using the random number ka, the element G, and the prime number q, and

said shared key generator calculates the shared key Ka on the elliptic curve E(F) by a formula: Ka = kayb mod q, using the public key yb = kbG mod q generated from the random number kb on the elliptic curve E(F) by the second user as the shared key distribution destination, and the random number ka.

12. (Canceled)

13. (Currently Amended) A key exchange apparatus including:

a random number generator for generating a random number ka that holds a relationship $0 < ka < q$, where an element in a finite group F for which multiplication is defined is g, and an order that is a prime number of the element g is q;

a secret key holding unit for temporarily holding the random number ka;

a public key generator for calculating a public key ya in the finite group F from the random number ka, the element g, and the prime number q; and

a shared key generator for calculating a shared key Ka in the finite group F using a public key yb generated from a random number kb which holds a relationship $0 < kb < q$ and is generated by a second user as a destination distribution of the shared key, and the random number ka that is held by the secret key holding unit,

wherein at least said random number generator, said secret key holding unit, said public key generator, and the shared key generator are formed on one semiconductor integrated circuit so as to prevent diversion or alteration of arithmetic algorithms of the public key generator and the shared key generator,

wherein the random number generator generates a new random number after the calculation of the shared key Ka is completed so that the public key ya and the shared key Ka become functions of the random number,

wherein said secret key holding unit holds the new random number generated by the random number generator,

wherein a controller of a first user as a distribution source of the shared key controls the random number generator and the public key generator to obtain the public key ya, and transmits the obtained public key ya to a second user as a distribution destination of the shared key, ~~and~~

wherein said controller obtains the public key yb from the second user as the shared key distribution destination, and controls the shared key generator to derive the shared key Ka, and

wherein the arithmetic algorithms of the public key generator and the shared key generator are not revealed outside of the one semiconductor integrated circuit.

14. (Previously Presented) The key exchange apparatus of Claim 13, wherein

the public key generator calculates the public key ya in the finite group F using the random number ka, the element g, and the prime number q by a formula: ya = g^ka mod q, and

the shared key generator calculates the shared key Ka in the finite group F by a formula: Ka = yb^ka mod q, using the public key yb = g^kb mod q that is generated in the finite group F from the random number kb by the second user as the shared key distribution destination, and the random number ka that is held in the secret key holding unit.

15. (Previously Presented) The key exchange apparatus of Claim 13, wherein

when the finite group F is an elliptic curve E(F) in a finite field, and an element on the elliptic curve E(F) is G,

the public key generator calculates the public key ya on the elliptic curve E(F) using the random number ka, the element G, and the prime number q by a formula: ya = kaG mod q, and

the shared key generator calculates the shared key Ka on the elliptic curve E(F) by a formula: Ka = Kayb mod q, using the public key yb = kbG mod q that is generated from the random number kb on the elliptic curve E(F) by the second user as the shared key distribution destination, and the random number ka that is held in the secret key holding unit.

16. (Previously Presented) The key exchange apparatus of Claim 13, wherein

the random number generator generates a new random number ka after the calculation of the public key ya is completed, and

the secret key holding unit holds the new random number ka generated by the random number generator.

17. (Canceled)

18. (Previously Presented) A key exchanging method that employs the key exchange apparatus of Claim 9, thereby exchanging the public keys that are generated by a first user and a second user that intend to exchange the public keys, respectively, to generate a shared key by the first user and the second user on the basis of the exchanged public key, respectively.

19. (Previously Presented) A key exchanging method that employs the key exchange apparatus of Claim 13, thereby exchanging the public keys that are generated by a first user and a second user that intend to exchange the public keys, respectively, to generate a shared key by the first user and the second user on the basis of the exchanged public key, respectively.

20. (New) The public key generation apparatus of claim 1,

wherein the public key generator uses the random key ka in the one semiconductor integrated circuit only for the calculation of the public key ya.

21. (New) The sharked key generation apparatus of claim 5,

wherein the shared key generator uses the random key ka in the one semiconductor integrated circuit only for the calculation of the shared key Ka.

22. (New) The key exchange apparatus of claim 9,

wherein the shared key generator uses the random key ka in the one semiconductor integrated circuit only for the calculation of the public key ya and the shared key Ka.

23. (New) The key exchange apparatus of claim 13,

wherein the shared key generator uses the random key ka in the one semiconductor integrated circuit only for the calculation of the public key ya and the shared key Ka.
